(54) Title: METHOD AND SYSTEM FOR CLIENT-SERVER INTERACTION IN INTERACTIVE COMMUNICATIONS

(57) Abstract

In an interactive communication system based on MPEG-4, Command descriptors along with Command Route nodes or Server Routes in the scene description can be used to support application-specific interactivity. Content selection can be supported by specifying the presentation in command parameters, with the command ID indicating that the command is a content selection command. An initial scene can be created with several images and with text that describes a presentation associated with an image. Associated with each image and the corresponding text is a content selection descriptor. When a user clicks on an image, the client transmits the command containing the selected presentation and the server starts a new presentation. The technique can be used in any application context, as generally as HTTP and CGI can be used to implement any server-based application functionality.

## METHOD AND SYSTEM FOR CLIENT-SERVER INTERACTION IN INTERACTIVE COMMUNICATIONS

### Technical Field

The present invention relates to techniques for performing client-server interaction in communication systems and, more particularly, in communication systems based on the MPEG-4 standard.

### 5 Background of the Invention

Interactivity is a prominent concern in the development of the MPEG-4 international standard (ISO/IEC 14496 Parts 1-6, Committee Draft, October 31, 1997, Fribourg, Switzerland). A back channel is specified for interactive message support. However, the syntax and semantics of the messages to be carried through that channel remain unspecified, and so does the mechanism that triggers the transmission of such messages. Existing standards such as DSM-CC (ISO/IEC International Standard 13818-6) and RTSP (RFC 2326) support traditional VCR-type interactivity to reposition a media stream during playback, but this is inadequate for MPEG-4 applications which require more complex interactive control.

15 An interactive message can be generated by a certain user action or system event. It will then be sent to the server which in turn may modify the stream(s) it is delivering by adding or removing objects, or switching to an entirely new scene. User actions may include clicking on an object, input of a text stream, etc. System events include timers, conditional tests, etc.

20 Interactivity is application-specific, and one cannot define interactive behavior completely in terms of user events. To support application-specific interactivity, a CGI-like approach should be adopted. Specific user events cause application-specific command data to be sent back to the server. The server can then respond, typically by sending a scene description update command. This allows complete freedom for supporting full interactivity as may be required by applications.

25 MPEG-4 essentially uses two modes of interactivity: local and remote. Local interactivity can be fully implemented using the native event architecture of MPEG-4 BIFS (Binary Format for Scenes), which is based on the VRML 2.0 ROUTEs design (see [www.vrml.org](http://www.vrml.org) and "The VRML Handbook", J. Hartman and J. Wernecke, Addison-Wesley, 1996) and documented in Part 1 of the MPEG-4 specification (Systems). If the MPEG-4 receiver is hosted in another application, events that need to be communicated to the MPEG-4 receiver by the application can be translated to BIFS update commands, as defined in Part 1 of MPEG-4.

30 Remote interactivity currently consists of URLs. As defined in the MPEG-4 Systems Committee Draft, these can only be used to obtain access to content. As a result, they cannot be used to trigger commands.

The fact that MPEG-4 Systems already contains local interactive support via the use of event source/sink routes that are part of the scene description (BIFS) makes it desirable to have a server interaction process that fully integrates with the local interactivity model.

5     Summary of the Invention

An objective of the present invention is to provide a technique for communicating messages between two entities such as "client" and "server", utilizing the MPEG-4 international standard.

10     A second objective of the present invention is to provide a technique for allowing the user or the system to generate such messages in the context of an MPEG-4 player or client.

A third objective is to provide a technique for generating such messages consistent with the local interactivity model defined in MPEG-4, which is based on the VRML 2.0 specification.

15     A further objective is to provide a technique for encoding such messages within an MPEG-4 bitstream, as well as to link the encoded messages to the scene description.

20     Still a further objective is to provide a technique for encoding such messages in a way that allows a server to easily modify them before sending them for use by the client. This is important for interactive applications. An example is "cookie" management where a server must be able to quickly update the content of the command with a codeword that stores state information about the user's activities on the particular site.

25     In order to meet these and other objectives which will become apparent with reference to further disclosure set forth below, the present invention broadly provides a technique for incorporating server commands into MPEG-4 clients. The technique involves the use of command descriptors, i.e. a special form of descriptors that are transmitted together with the scene description information and contain the command to be sent back to a server upon triggering of an associated event. The desired event sources in the scene description are associated with these command descriptors.

30     In one embodiment, the association is performed using server routes. These operate similarly to traditional MPEG-4 BIFS routes, but instead of linking a source field with a sink field they link a source field with a sink command descriptor. Server routes require an extension of the MPEG-4 BIFS ROUTE syntax.

35     In another embodiment, the association is performed using command nodes. Such nodes contain sink fields, and are associated with command descriptors. This technique involves the addition of one more node type to the set of MPEG-4 BIFS nodes.

In both cases, the normal interaction model defined by MPEG-4 can be used

Fig. 12 is a flow diagram illustrating the process of triggering a server command in an MPEG-4 client, when Server Routes are used.

10

#### Detailed Description

Reference will now be made in detail to the preferred embodiment of the invention as illustrated in the figures.

15 MPEG-4 is an international standard being developed under the auspices of the International Standardization Organization (ISO). Its official designation is ISO/IEC 14496. Its basic difference with previous ISO or ITU standards such as MPEG-1, MPEG-2, H. 261, or H. 263 is that it addresses the presentation of audiovisual objects. Thus, the different elements comprising an audiovisual scene are first encoded separately, using techniques that are being defined in Parts 2 (Visual) and 3 (Audio) of the specification. These objects are transmitted to the receiver or read from a mass storage device together with scene description information that describes how these objects are to be placed in space and time in order to be presented to the user.

25 The coded data for each audiovisual object as well as the scene description information proper are transmitted in their own "channels" or elementary streams. Additional control information is also transmitted, as further discussed below, in order to allow the receiver to correctly associate audio visual objects referenced in the scene with the elementary streams that contain their encoded data.

30 In order to fully describe the structure of MPEG-4, we refer to Fig. 1. At the bottom of the figure, the various possible delivery systems are shown, including (but not limited to) ATM, IP, MPEG-2 Transport Stream (TS), DVB, either over a communication link or a mass storage device. In contrast to MPEG-2, MPEG-4 does not define its own transport layer facility, in order to allow delivery over a wide variety of communication environments. For delivery systems that may lack appropriate multiplexing capability, e.g. GSM wireless data channels, or that require low delay, a simple multiplexing tool called FlexMux is defined.

35 This infrastructure is used to deliver to the client a set of elementary streams. The streams contain any one of scene description information, audio visual object data (e.g. coded video, such as an MPEG-2 or MPEG-4 video stream), or control information (namely, object descriptors). Each elementary stream can contain data of

40

for both local interactivity, i.e. events generated and processed on the local clients, as well as server interactivity, i.e. as events generated on the client generate commands that are sent back to the server. Upon triggering of an event associated with a command descriptor, either via a server route or a regular route to a command node, the client obtains the command information stored in the command descriptor, packages it into a command message, preferably using the syntax provided in the preferred embodiment, and transmits it back to the server using the appropriate back channel.

The data to be carried by the generated command back to the server are contained in the command descriptor. Since command descriptors are part of the overall descriptor framework of MPEG-4, they can be dynamically updated, using time stamped object descriptor updates. This provides considerable flexibility in customizing commands, for example to perform "cookie" management.

To further aid the server in processing the generated command, additional information such as the time the event was generated, the source node, etc., are also contained in the client's message.

#### Brief Description of the Drawing

Fig. 9 shows the node syntax and semantics of the Command Route structure.

Fig. 10 shows an indicative list of predefined Command IDs and their associated interpretation.

Fig. 11 shows the binary syntax of the command contained in a command descriptor for the preferred embodiment.

VRML is a purely 3-D scene description language. This addresses the needs of applications that focus on low-cost systems. In contrast to VRML, MPEG-4 does not use a text-based scene description but instead defines a bandwidth-efficient compressed representation called BIFS (Binary Format for Scenes).

5       The BIFS encoding follows closely the textual specification of VRML scenes. In particular, node coding is performed in a depth-first fashion, similarly to text-based VRML files. As in VRML, the fields of each type of node assume default values. Hence only fields that have non-default values need to be specified within each node. Field coding within a node is performed using a simple index-based method followed  
10       by the value of the coded field. Node type coding is more complicated. In order to further increase band width efficiency the context of the parent field (if any) is taken into account. Each field that accepts children nodes is associated with a particular node data type. Nodes are then encoded using an index which is particular to this node data type, in known fashion.

15       Each coded node can also be assigned a node identifier (an integer, typically). This allows the reuse of that node in other places in the scene. This is identical to the USE/DEF mechanism of VRML. More important, however, is the fact that it allows it to participate in the interaction process.

20       The interaction model used in MPEG-4 is the same as in VRML. In particular, fields of a node can act as event sources, event sinks, or both. An event source is associated with a particular user action or system event. Example of user event are sensor nodes that can detect when the mouse has been clicked. Example of system events are timers (TimeSensor node) that are triggered according to the system's time.

25       Dynamic scene behavior and interactivity are effected by linking event source fields to event sink fields. The actual linking is performed using the mechanism of ROUTEs. MPEG-4 route specifications, if any, are given immediately after the scene node descriptions. Their encoding is based on the node identifiers for the source and sink nodes, as well as the field indices of the source and sink fields.

30       An important distinction between VRML and MPEG-4 is that in the latter, scene descriptions can be updated dynamically using time-stamped commands. In Contrast, VRML operates on static "worlds". After a world is loaded, there is no mechanism to modify it. In MPEG-4, objects can be added or deleted, and parts of the scene (or the entire scene) can be replaced.

### 35                               OBJECT DESCRIPTORS

      In order to have a very flexible structure (facilitating editing, etc.), the actual content of audiovisual objects is not contained within the scene description itself. In other words, BIFS only provides the information for the scene structure, as well as objects that are purely synthetic, e.g. a red rectangle that is constructed using

only one type.

The data contained in an elementary stream are packaged according to the MPEG-4 Sync Layer (SL), which packages access units of the underlying medium (e.g., a frame of video or audio, or a scene description command) and adds timing information (clock references and time stamps), sequence numbers, etc. The SL is shown at the middle portion of Fig. 1.

Encoding of individual audiovisual object data is performed according to Parts 2 and 3 of the MPEG-4 specification. It is furthermore allowed to utilize other encodings, such as MPEG-1 or MPEG-2. The scene description as well as the control information (object descriptors) is encoded as defined in Part 1 of MPEG-4.

The receiver processes the scene description information as well as the decoded audiovisual object data and performs composition, i.e. the process of combining the objects together in a single unit, and rendering, i.e. the process of displaying the result in the user's monitor or playing it back in the user's speaker is in the case of audio. This is shown at the top of Fig. 1.

Depending on the information contained in the scene description, the user may have the opportunity to interact with the scene. In addition, the scene description may contain information that enables dynamic behavior. In other words, the scene itself may generate events, without user intervention.

The object-based structure of MPEG-4 necessitated the definition of a more general system decoder model compared with MPEG-2 or other systems. In particular, as shown in Fig. 2, the receiver is considered to be equipped with a set of decoders, one for each object. Each decoder has a decoding buffer, as well as a composition buffer. Decoding buffers are managed by the sender using techniques similar to MPEG-2, i.e., clock references for clock recovery, and decoding time stamps for removal of data from the decoding buffer followed by theoretically instantaneous decoding. Data placed in composition buffers are available for use by the compositor, and overwrite any previously placed data. The decoding buffers are filled by the demultiplexer, which is encapsulated within the DMIF (Digital Media Integration Framework, Part 6 of MPEG-4) Application Interface. This is a conceptual interface, requiring no further description here.

#### MPEG-4 SCENE DESCRIPTION

The scene description information in MPEG-4 is an extension of VRML 2.0 (Virtual Reality Modeling Language) specification. VRML uses a tree structured approach to define scenes. Each node in the scene performs a composition and/or grouping operation, with the leaves containing the actual visual or audio information. Furthermore, nodes contain fields that affect their behavior. For example, a Transform node contains a Rotation field to define the angle of rotation.

MPEG-4 defines some additional nodes that address 2-D composition, as

server, or trigger the generation of such messages.

Fig. 4 depicts an example client/server environment. On the left side of the figure there is an MPEG-4 server, including a pump that performs timed transmission of data read as SL-packetized streams, and an instance of a DMIF service provider, in this case utilizing the MPEG-4FlexMux multiplexing tool.

The use of FlexMux is optional. Other server structures can be used, as known in the art. For example, the data source could be an MPEG-4 file instead of SL-packetized streams.

The information generated at the server is sent across a network (e. g. IP or ATM) to the receiver. On the receiving side, we have a similar instance of a DMIF service provider which delivers demultiplexed elementary streams to the player. The DMIF-to-DMIF signaling is one method of performing session set up, and is described in Part 6 of MPEG-4. Other methods are possible, as known in the art, including Internet-based protocols such as SIP, SDP, RTSP, etc.

One of the main objectives of the present invention is a process with which server commands can be first described and transmitted from the server to the client, then triggered at the client at the appropriate times, and finally sent back to the server in order to initiate further action.

#### COMMAND DESCRIPTORS

The Command Descriptor framework provides a means for associating commands with event sources within the nodes of a scene graph. When a user interacts with the scene, the associated event is triggered and the commands are subsequently processed and transmitted back to the server.

The actual interaction itself is specified by the content creator and may be a mouse click or mouse-over or some other form of interaction (e.g., a system event).

The command descriptor framework consists of three elements, a Command Descriptor, a server route or Command Route node, and a Command.

A Command Descriptor contains an ID (an integer identifier) as well as the actual command that will eventually be transmitted back to the server if and when an associated event is triggered.

The ID is used to refer to this command descriptor from the scene description information. By separating the command descriptor and the command it contains from the scene itself, we allow for more than one event to use the same command. This also permits modification of the command without changing the scene description in any way.

The association of the Command Descriptors to the event source field node can be performed in different ways.

First, a Server Route can be added to the regular route facility of BIFS. The difference with traditional routes is that the target of the route is not another field, but

BIFS/VRML nodes. Audio visual objects that require coded information are represented in the scene by leaf nodes which either point to a URL or an object descriptor.

5 Object descriptors are hierarchically structured information that describe the elementary streams that comprise the coded representation of a single audio visual object. More than one stream may be required, e.g. for stereo or multi-language audio, or hierarchically coded video. The topmost descriptor is called object descriptor, and is a shell that is used to associate an object descriptor identifier (OD-ID) with a set of elementary stream descriptors. The latter contain an ES-ID as well  
10 as information about the type of data contained in the elementary stream associated with the particular ES-ID. This information tells the receiver, e.g., that a stream contains MPEG-2 Video data, following the Mail Profile at the Main Level.

The mapping of the ES-ID to an actual elementary stream is performed using a stream map table. For example, it may associate ES-ID 10 with support number  
15 1025. This table is made available to the receiver during session set up. The use of multiple levels of indirection facilitates manipulation of MPEG-4 content. For example, remultiplexing would only require a different stream map table. No other information would have to be modified within the MPEG-4 content.

Object descriptors are transmitted in their own elementary streams, and are  
20 packaged in commands according to the Sync Layer syntax. This allows object descriptors to be updated, added, or removed.

Fig. 3 depicts the process with which object descriptors and elementary stream descriptors are used to associate audiovisual objects in the scene description with their elementary streams. First, a special Initial Object Descriptor is used to bootstrap the  
25 MPEG-4 receiver by pointing to the object descriptor stream and the scene descriptor stream associated with the selected content. This descriptor is delivered to the receiver during session set up.

The scene description in this example contains an Audio Source node, which points to one of the object descriptors. The descriptor, in turn, contains an elementary  
30 stream descriptor that provides the ES-ID for the associated stream. The ES-ID is resolved to an actual transport channel using the stream map table. The scene also has a Movie Texture node that, in this case, uses scalable video with two streams. As a result, two elementary stream descriptors are contained, each pointing to the appropriate stream (base and enhancement layer).

### 35 MPEG-4 CLIENT/SERVER INTERACTION

From the preceding description, and considering the MPEG-4/VRML scene description framework, it is evident that while a rich local interaction framework is provided, there is no facility to effect server-based interaction. In particular, there is no mechanism with which to either describe messages that are to be sent back to a

rather the command descriptor. This structure is depicted in Fig. 5(a). In this example we have two nodes in a scene tree fielding events to two command descriptors. A sensor node triggers an event to another node with an event source, event out, or event source/sink, exposed Field in MPEG-4 terminology, which in turn is routed via a server route to Command Descriptor 1. For Command Descriptor 2, there are direct server routes from the nodes to the descriptor.

A second approach consists of adding a new Command Route node type to the list of nodes supported by MPEG-4. This node has an 'execute' event sink field, as well as a field containing the command descriptor ID. Whenever the 'execute' field receives an event, using regular MPEG-4/VRML routes, the command descriptor associated with that ID is used to issue a command back to the server. This structure is depicted in Fig. 5(b). As compared with Fig. 5(a), the Server Routes are substituted with Command Route nodes. The operation in the two cases is essentially the same.

The Command Descriptor syntax is shown in Fig. 6. We use the Flavor media representation language to describe the bit stream syntax, which is also used in Part 1 of the MPEG-4 specification (see [www.ee.columbia.edu/flavor](http://www.ee.columbia.edu/flavor) or Part 1 of MPEG-4). The command descriptor begins with a special tag that identifies it as a descriptor of this particular type. We then have the descriptor ID, followed by a command ID. The latter is used to signal predefined server commands, such as "start", "pause", or "stop". Following that, we have the length indication of the remaining data in the descriptor, counted in bytes. Then, a count of the number of ES-IDs that will be provided to transmit the message back to the server(s). More than one is given in case we want to effect one-to-many communication, i.e. a single command to be communicated to multiple servers. This is followed by the series of the desired ES-IDs. Finally, a set of application-specific parameters are included. These will be passed back to the server when the command is triggered. Depending on the value of the command ID, the semantics of these parameters may be predefined.

The byte-oriented structure of the Command Descriptor allows it to be very easily generated on-the-fly by the server. This is an important feature for applications that involve "cookie" management, among others, where the command parameters need to be continuously updated by the server after processing each user event.

In order to update a Command Descriptor, the server or content creator only needs to submit a new one with the same ID.

In order to remove a Command Descriptor, a special command is provided. The syntax is shown in Fig. 7. The command begins with a tag that identifies this descriptor as a Command Descriptor Remove command. It is then followed by the ID of the Command Descriptor to be removed.

Both the Command Descriptor and Command Descriptor Remove structures can be carried within the object descriptor stream. Due to the structure of the object descriptor framework, using tags to identify descriptors, these can be interspersed

## CLAIMS

1. A method for communicating command information between a server and a client in an interactive communication system, comprising:  
generating a command message including a command, a command descriptor, and one of a server route and a command node; and  
transmitting the command message upon occurrence of a triggering event.
2. The method in accordance with claim 1, wherein the interactive communication system is based on MPEG-4.
3. The method in accordance with claim 2, wherein generating the command message is consistent with the local interactivity model defined in MPEG-4.
4. The method in accordance with claim 1, wherein the triggering event is a mouse click.
5. The method in accordance with claim 1, wherein the triggering event is a timer signal.
6. The method in accordance with claim 1, wherein command information is transmitted from the server to the client.
7. The method in accordance with claim 1, wherein command information is transmitted from the client to the server.
8. An interactive communication system comprising means for communicating command information between a server and a client, wherein the means for communicating command information comprises:  
means for generating a command message including a command, a command descriptor, and one of a server route and a command node; and  
means for transmitting the command message upon occurrence of a triggering event.
9. The system in accordance with claim 8, based on MPEG-4.
10. The system in accordance with claim 9, wherein generating the command message is consistent with the local interactivity model defined in MPEG-4.
11. The system in accordance with claim 8, wherein the triggering event is a

was transmitted, as well as the set of parameters that were specified in the Command Descriptor. These commands are transmitted in SL-packetized streams, and hence full timing and sequencing information can be made available to the server.

#### PROCESSING EVENTS FOR DISPATCHING SERVER COMMANDS

5 We now discuss in detail the process of generating commands based on user or system events, starting with the use of Server ROUTEs.

Referring to Fig. 12, upon the generation of a user or system event, the receiver propagates the event through the network of ROUTEs and Server ROUTEs. For the purposes of event propagation, the type of ROUTE does not matter, so that  
10 the same algorithm can be used. If an event is propagated through a Server Route, the system checks if that event corresponds to a condition associated with the logical True value. If no, the server command processing terminates; yes, then the dispatch process is executed.

This process, for the Server Route case, is depicted in Fig. 13. The process  
15 obtains the Command Descriptor ID from the Server Route. It then correlates it with the information it has on the Command Descriptors available in the scene. If no match is found, this is an error and no further action is taken. If a match is found, then the system examines the command ID in order to see if it corresponds to known semantics (pre-defined command IDs). If it corresponds to known semantics then the  
20 system may process the command parameters according to the desired semantics. If it does not correspond to known semantics then the system skips this state, and directly packages the indicated Command and transmits it to the server.

In the case of Command Route nodes, referring to Fig. 14, upon the  
25 generation of a user or system event, the receiver propagates the event through the network of ROUTEs. If an event reached the 'execute' field of a Command Route node, the system check if that event corresponds to a condition associated with the logical True value. If no, server command processing terminates; if yes, the dispatch process is executed.

This process, for the Command Route node case, is depicted in Fig. 15. The  
30 sequence of steps is essentially identical to that of Fig. 13, the difference being that the reference for the Command Descriptor ID is now in the Command Route node rather than a Server Route.

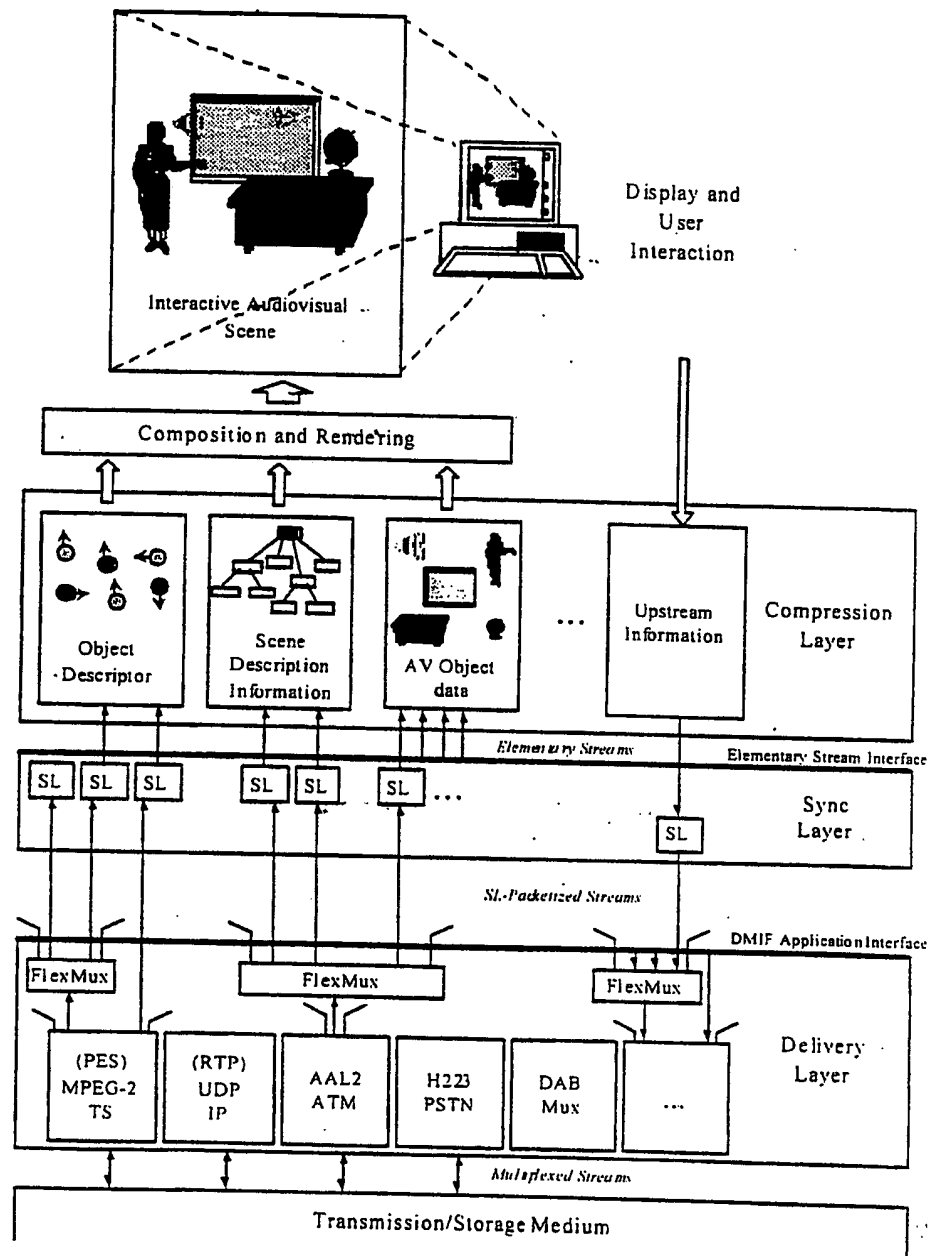

FIG. 1

mouse click.

12. The system in accordance with claim 8, wherein the triggering event is a timer signal.

13. The system in accordance with claim 8, wherein command information is transmitted from the server to the client.

14. The system in accordance with claim 8, wherein command information is transmitted from the client to the server.

FIG. 5

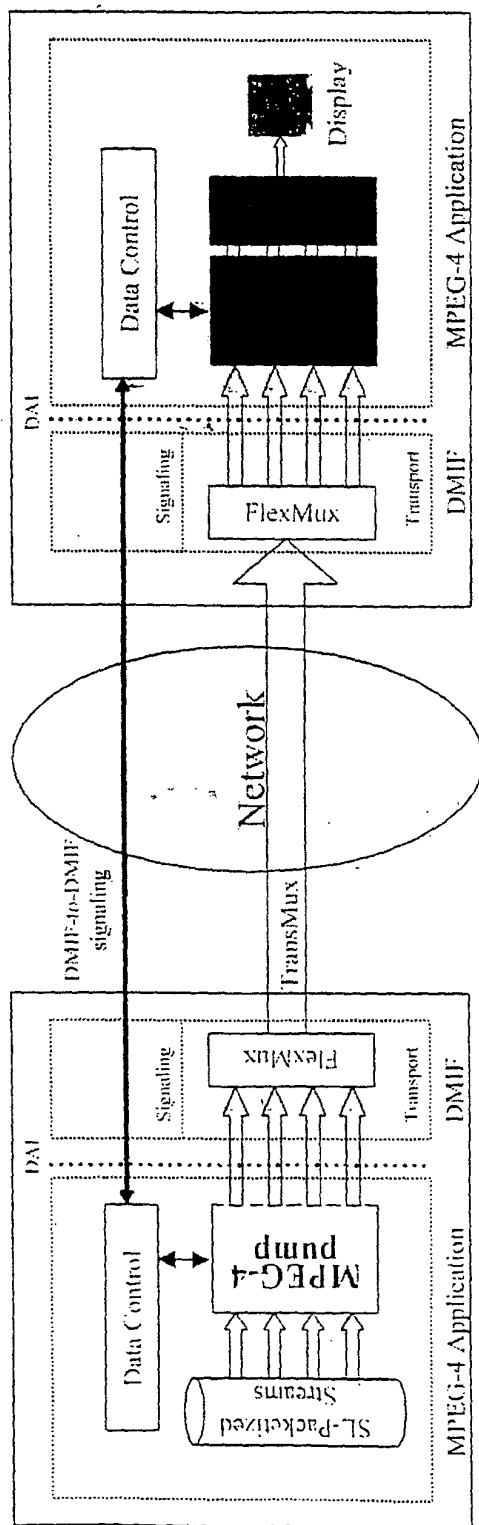

FIG. 4

## CommandRoute

### Node interface

```

CommandRoute {
    eventIn      SFBool      Execute      FALSE
    field        SFUrl       CommandDescriptor
}

```

### Functionality and semantics

The **CommandRoute** node is used to support server interaction. A command route is executed when an event is received on the **execute** field, for example, from a touch sensor. The execution of a command route involves communicating the command pointed by the **commandDescriptor** to the server. The **commandDescriptor** field contains either a URL to the command descriptor or the ID of the Command Descriptor to be associated with this **CommandRoute** node. Commands are typically sent to a server using DMIF's **DAI\_User\_Command** primitives. The node update mechanism can be used to change the command descriptor ID. This allows supporting different interaction behavior for the same user interaction at different times (before and after node update).

FIG. 9

Command Name	Command ID
Unused	0X0000
Start	0X0001
Stop	0X0002
Pause	0X0003
Forward	0X0004
Reverse	0X0005
ContentSelection	0X0006
MPEG-4 reserved	0X0007 - 0X00FF
User Defined	0X0100 - 0XFFFF

FIG. 10

```

class CommandDescriptor: bit(8) CommandDescriptorTag = 0x05 {
    bit(16) CommandDescriptorID;
    bit(16) CommandID;

    bit(16) length;

    // stream count; number of ES_IDs associated with this message
    unsigned int (8) count;

    // ES_Id (channel numbers) of the streams affected by the command
    unsigned int (16) ES_ID[count];

    // application-defined parameters
    do {
        unsigned int (8) paramLength;
        char (8) commandParam [paramLength];
    }
    while (paramLength!=0);
}

```

FIG. 6

```

class CommandDescriptorRemove: bit(8) CommandDescriptorRemoveTag = 0x06 {
    bit(16) CommandDescriptorID;
}

```

- FIG. 7

```

class BIFSScene {
    SFNode nodes(SFTopNode);
    bit(1) hasROUTES;
    if (hasROUTES)
        ROUTEs routes ;
    bit(1) hasServerROUTES;
    // the following is added to the MPEG-4 syntax
    if (hasServerROUTES)
        ServerROUTES sroutes;
}

// modification of MPEG-4 ROUTEs structure to point to command descriptor
class ServerROUTES {

    bit(1) isUpdateable;
    if (isUpdateable)
        bit(10) srouteID;

    bit(10) outNodeID;
    NodeData nodeOUT = GetNodeFromID(outNodeID); // get source node
    int (nodeOUT.nOUTbits) outFieldRef; // event source field index

    bit(10) CD_ID; // event sink - command descriptor ID
}

```

FIG. 8

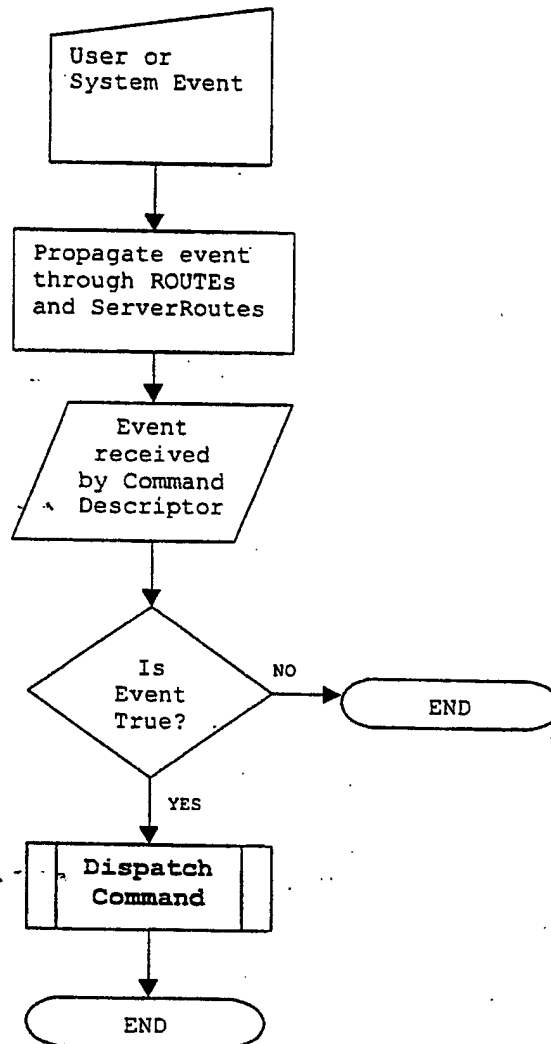

FIG. 12

```
class Command {  
    // command ID  
    bit(16) CommandID;  
  
    // the following are simply copied from the command descriptor  
    // stream count; number of ES_IDs associated to this message  
    unsigned int (8) count;  
  
    // ES_Id of the streams  
    unsigned int (16) ES_ID[count];  
  
    // application-defined parameters  
    do {  
        unsigned int (8) paramLength;  
        char (8) commandParam[paramLength];  
    }  
    while (paramLength!=0);  
}
```

## INTERNATIONAL SEARCH REPORT

International application No.  
PCT/US99/02063

## A. CLASSIFICATION OF SUBJECT MATTER

IPC(6) : G06F 13/00; G06F 13/14

US CL : 709/203

According to International Patent Classification (IPC) or to both national classification and IPC

## B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 709/203,208,238,239,240,244,100; 370/236,270,282,389,390,392,474,524; 345/327; 348/7,8,9,10,11,12

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS;INTERNET SEARCHES

## C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X — Y	US 5,621,892 A (COOK) 15 APRIL 1997 Column 4, 10-49; Column 5, Lines 3-59	1,5,7,8,12, 14 — 2,3,9,10
X — Y	US 5,671,225 A (HOOPER et al.) 23 SEPTEMBER 1997 Column 2, Lines 10-20; Column 4, Lines 8-28; Column 5.	1,4,6,7,8,11,13, 14 — 2,3,9,10
Y	"Video-on-Demand"; TAMPERE UNIVERSITY OF TECHNOLOGY, FINLAND; Last modified 20 MARCH 1995; Retrieved from Internet at URL: <a href="http://www.cs.tut.fi/tlt/stuff/vod/VoDOverview/vod.html">http://www.cs.tut.fi/tlt/stuff/vod/VoDOverview/vod.html</a> Pages (14-16,19-20)/27, under headings "Standards" and "DSM-CC"	2,3,9,10

☒ Further documents are listed in the continuation of Box C. ☐ See patent family annex.

* Special categories of cited documents:	*T* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
*A* document defining the general state of the art which is not considered to be of particular relevance	*X* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
*B* earlier document published on or after the international filing date	*Y* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
*L* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*A* document member of the same patent family
*O* document referring to an oral disclosure, use, exhibition or other means	
*P* document published prior to the international filing date but later than the priority date claimed	

Date of the actual completion of the international search

09 APRIL 1999

Date of mailing of the international search report

13 MAY 1999
